

Where,

$\Lambda_c =$  Equivalent Conductance of 'C' concentration.

$\Lambda_\infty =$  Equivalent Conductance of  $\infty$  dilution.

This is approximately true for weak electrolytes but not in strong electrolytes.

\*. Kohlrausch's Law :-

A/c to Kohlrausch -

The dissociation of any electrolyte is complete at  $\infty$  (infinite) dilution and there is no inter-ionic effect at this dilution.

So, He concluded that -

Both cations and anions contributed independently towards equivalent conductance. Hence, He stated his law as -

Equivalent Conductance of an electrolyte at infinite dilution ( $\infty$ ) is composed of two factors - one contributed by cation and the other contributed by an anion. i.e.

$$\Lambda_\infty = \nu^+ \lambda^+ + \nu^- \lambda^-$$

Where,  $\lambda^+, \lambda^-$  are the ionic conductance of cation & anion.  
 $\nu^+, \nu^-$  are their valencies.

## Application of Kohlrausch's law:-

(7)

(1) Determination of molar conductivity of weak electrolyte at infinite dilution. ( $\Lambda_{\infty}$ ).

It is determined with the help of molar conductivity of strong electrolyte.

for eg -

Given,

$$\Lambda_{\infty} \text{C}_2\text{H}_5\text{COONa} = 85.1 \text{ ohm}^{-1} \text{cm}^2 \text{eq}^{-1}$$

$$\Lambda_{\infty} \text{HCl} = 426.3 \text{ " " " "}$$

$$\Lambda_{\infty} \text{NaCl} = 126.1 \text{ " " " "}$$

$$\Lambda_{\infty} \text{C}_2\text{H}_5\text{COOH} = ?$$

$$\Lambda_{\infty} \text{C}_2\text{H}_5\text{COONa} = \lambda_{\text{C}_2\text{H}_5\text{COO}^-} + \lambda_{\text{Na}^+} = 85.1 \text{ ohm}^{-1} \text{cm}^2 \text{eq}^{-1} \quad \text{--- (1)}$$

$$\Lambda_{\infty} \text{HCl} = \lambda_{\text{H}^+} + \lambda_{\text{Cl}^-} = 426.3 \text{ " " " "} \quad \text{--- (2)}$$

$$\Lambda_{\infty} \text{NaCl} = \lambda_{\text{Na}^+} + \lambda_{\text{Cl}^-} = 126.1 \text{ " " " "} \quad \text{--- (3)}$$

$$\Lambda_{\infty} \text{C}_2\text{H}_5\text{COOH} = \lambda_{\text{C}_2\text{H}_5\text{COO}^-} + \lambda_{\text{H}^+} = ?$$

on adding eqs (1) & (2) and then subtracting eq (3)

We get -

$$\lambda_{\text{C}_2\text{H}_5\text{COO}^-} + \cancel{\lambda_{\text{Na}^+}} + \lambda_{\text{H}^+} + \cancel{\lambda_{\text{Cl}^-}} - \cancel{\lambda_{\text{Na}^+}} - \cancel{\lambda_{\text{Cl}^-}} = 85.1 + 426.3 - 126.1$$

$$\lambda_{\text{C}_2\text{H}_5\text{COO}^-} + \lambda_{\text{H}^+} = 385.3$$

$$\text{ohm}^{-1} \text{cm}^2 \text{eq}^{-1}$$

$$\therefore \Lambda_{\infty} \text{C}_2\text{H}_5\text{COOH} = 385.3 \text{ ohm}^{-1} \text{cm}^2 \text{eq}^{-1}$$

② Determination of degree of dissociation ( $\alpha$ ) for weak electrolyte.

It is determined from the formula:-

$$\alpha = \frac{\Lambda_c}{\Lambda_{\infty}}$$

$\Lambda_c$  = molar conductivity of the electrolyte at any concentration.

$\Lambda_{\infty}$  = molar conductivity of the electrolyte at infinite dilution.

$\alpha$  = degree of dissociation of weak electrolyte.

③ Determination of dissociation constant ( $K_c$ ) of weak electrolytes -

We know that an equilibrium constant -

$$K_c = \frac{c\alpha^2}{1-\alpha}$$

for weak acid  $K_a = \frac{c\alpha^2}{1-\alpha}$

for weak base  $K_b = \frac{c\alpha^2}{1-\alpha}$

This formula is not applicable to strong electrolytes such as NaCl, NaOH, AgNO<sub>3</sub>, CuSO<sub>4</sub>, HNO<sub>3</sub> etc. because, strong electrolytes are almost 100% dissociated in aq. solns.
